Secure File Upload System with S3

ABSTRACT

The **Secure File Upload System using Amazon S3** is a web-based application that enables users to upload, store, and securely access files in the cloud. The system is built on Amazon Web Services (AWS), providing a scalable and reliable storage solution for handling user data efficiently.

This application allows authenticated users to upload files to an S3 bucket, where they are stored with high durability and availability. To ensure security, the system generates pre-signed URLs (temporary access links) for file downloads, preventing unauthorized access. Basic authentication mechanisms are implemented to verify users before allowing upload or download operations.

Key Features:

- Secure file upload to cloud storage (S3 bucket)
- Generation of time-limited download links (pre-signed URLs)
- Basic user authentication for access control
- Efficient file management with high scalability
- Protection of sensitive data using IAM roles and policies

Project Highlights:

- Uses IAM (Identity and Access Management) for permission control
- Minimal backend logic with maximum use of AWS configuration
- Demonstrates real-world cloud storage implementation
- Ensures data security and controlled accessibility

Conclusion:

The project showcases how cloud services can be integrated with simple web technologies to build a secure and scalable file management system. It provides hands-on experience with AWS services and highlights best practices in secure file handling and access control, making it highly relevant for modern application development.
